Abstract

random sequence generator based on them is suggested. by a variety of empirical, combinatorial, statistical, dynamical systems theory and computation theory methods. An efficient simplicity of this rule, the time sequences of site values that it yields seem to be completely random. These sequences are analysed or 1, and is updated in parallel according to the rule $a_i = a_{i-1}$ XOR $(a_i \text{ OR } a_{i+1})$ $(a_i = (a_{i-1} + a_i + a_{i+1} + a_i a_{i+1}) \text{ mod } 2)$. Despite the A 1-dimensional cellular automaton which generates random sequences is discussed. Each site in the cellular automaton has value 0

1. Random Sequence Generation

Sequences that seem random are needed for a wide variety of purposes. They are used for unbiased sampling in the Monte Carlo choices. And their unpredictability is used in games of chance, and potentially in data encryption. method, and to imitate stochastic natural processes. They are used in implementing randomized algorithms which require arbitrary

certainly does exist. (1) The sequence can nevertheless seem random if no computations done on it reveal this simple description. (e.g., [2]). But if in fact the sequence can be generated by iteration of a definite transformation, then a simple description of it transformation to it, progressively extracting as long as possible a random sequence (e.g., [1]). In general one considers a sequence `random" if no patterns can be recognized in it, no predictions can be made about it, and no simple description of it can be found To generate a random sequence on a digital computer, one starts with a fixed length seed, then iteratively applies some The original seed must be transformed in such a complicated way that the computations cannot recover it.

can yet be proved, so one must for now rely on more circumstantial evidence for adequate degrees of randomness recognized in certain sequences by any computation whatsoever that, for example, takes less than a certain time. No such results every element occurred purely according to probabilities. It would be better if one could show in general that patterns could not be simple computations encountered in practice, and check that statistical properties of the sequence agree with those predicted if Monte Carlo integration if the values it yields are distributed sufficiently uniformly. The existence say of particular correlations not sophisticated enough to be able to find patterns in the sequence. So, for example, a sequence might be random enough for time, there is a limit to the degree of randomness that the sequence need have. Statistical tests of randomness emulate various the sequence might not be discerned in this calculation. Whenever a computation that uses a random sequence takes a bounded A sequence is `random enough" for application in a particular system if the computations that the system effectively performs are The degree of randomness of a sequence can be defined in terms of the classes of computations which cannot discern patterns in it.

quite simple transformations, when iterated, can yield extremely complicated behaviour. Simple computations are able to produce sequences whose origins can apparently be deduced only by much more complex computations. The fact that acceptably random sequences can indeed be generated efficiently by digital computers is a consequence of the fact that

seeds), and limits their degree of randomness. $x' = ax + b \mod n$) (e.g., [1]), or linear feedback shift registers [4] (analogous to the linear cellular automata discussed below). The Most current practical random sequence generation computer programs are based on linear congruence relations (of the form properties to be proved [1, 4]. But it also leads to efficient algebraic algorithms for predicting the sequences (or deducing their linearity and simplicity of these systems has made complete algebraic analyses possible and has allowed certain randomness

exponential time computations) sequence, then the sequence would be random enough for almost any practical application (so long as it involved less than which takes a time at most 0(23). But if in fact such an exponentially long computation were needed to find any pattern in the most kinds of computers). It is always possible to deduce the seed (say of length 3) for such a sequence by an exhaustive search An efficient random sequence generator should produce a sequence of length L in a time at most polynomial in L (and linear on

seed for certain sequences was NP-complete [5]: special instances of the problem would then correspond to arbitrary problems in computationally equivalent to a large class of others. So, for example, one could potentially show that the problem of deducing the No such lower bounds on computational complexity are yet known. It is however often possible to show that one problem is polynomial time) includes many well-studied problems (such as integer factorization), which involve finding objects (such as prime reducibility to ensure that the problem is difficult almost always, as well as in the worst case.) The class NP (nondeterministic the class NP, and the problem would in general be as difficult as any in NP. (One should also show some form of uniform factors) that satisfy polynomial-time-testable conditions, but for which no systematic polynomial time (P) algorithms have ever

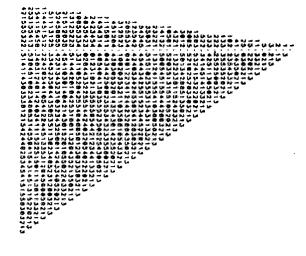

complete). An example is the sequence of least significant bits obtained by iterating the transformation $*' = *^2 \mod (pq)$, where p and principle equivalent to solving certain difficult number theoretical problems [2] (which are in the class NP, but are not NPinteger pq [6, 7]. Random sequence generators have been constructed with the property that recognizing patterns in the sequences they produce is in g are large primes (congruent to 3 modulo 4) [6]. Making predictions from this sequence is in principle equivalent to factoring the

seems random [10]. (Though again not even its normality has actually been proved.) Given the complete number obtained at a pattern shown in Fig. 1.1 The center vertical column of values, corresponding to the leading digit in the fractional part of (2)°, procedures have revealed any regularity in say the digit sequence of $\sqrt{2}$ (e.g., [8]). (Not even its normality or equidistribution has they seem random. An example is taking square roots of integers. Despite the simplicity of its computation, no practical statistical deduce the seed. particular stage, multiplication by (3) suffices to reproduce the original seed. But given only the center column, it seems difficult to however actually been proved.) An even simpler example is multiplication by $\frac{3}{2}$, say in base 6. (2) Starting with 1, one obtains the There are in fact many standard mathematical processes which are simple to perform, yet produce sequences so complicated that

Many physical processes also yield seemingly random behaviour. In some cases, the randomness can be attributed to the effects of

only suggest practical methods for random sequence generation, but also provide further understanding of the nature and origins of external random input. Thus, for example, `analog" random sequence generators such as noise diodes work by sampling thermal definite correlations. One suspects in fact that randomness in many physical systems (probably including turbulent fluids) arises not cases, sequences extracted sufficiently quickly can depend on only a few components of the environment, and must eventually show depend sensitively on initial velocities determined by complex systems with many components. It seems however that in all such randomness in physical processes. sequences by simple procedures which seem to capture many features of this phenomenon. The investigations described may not fluctuations associated with a heat bath containing many components. Coin tossings and Roulette wheels produce outcomes that from external random input, but rather through intrinsic mathematical processes [11]. This paper discusses the generation of random

Successive powers of 3/2 in base 6. The leading digits in the fractional parts of these numbers form a sequence that seems random. The process of multiplication by 3/2 in base 6 corresponds to a k=6, r=1 cellular automaton rule.

2. Cellular Automata

in parallel (synchronously) in discrete time steps according to a fixed rule of the form A 1-dimensional cellular automaton [12, 13] consists of a line of sites with values α_i between 0 and k-1. These values are updated

(2.1)
$$a_i^l = \phi(a_{i-r}, a_{i-r+1}, \dots, a_{i+r}).$$

Much of this paper is concerned with the study of a particular k=2, r=1 cellular automaton, described in Section 3

boundary conditions, given in the r=1 case by For mathematical purposes, it is often convenient to consider cellular automata with an infinite number of sites. But practical implementations must contain a finite number of sites N. These are typically arranged in a circular register, so as to have periodic

(2.2)
$$a'_1 = \phi(a_N, a_1, a_2)$$

 $a'_N = \phi(a_{N-1}, a_N, a_1)$

It is also possible to arrange the sites in a feedback shift register (cf. [4]), with boundary conditions

(2.3)
$$a'_1 = \phi(\phi(a_2, a_3, a_4), \phi(a_3, a_4, a_5), a_1),$$

 $a'_2 = \phi(\phi(a_3, a_4, a_5), a_1, a_2).$

mappings on the Cantor set (e.g., [15]). Finally they can be viewed as computational systems, whose evolution processes wide variety of natural systems (e.g., [14]). They can also be considered as discrete dynamical systems corresponding to continuous Cellular automata can be considered as discrete approximations to partial differential equations, and used as direct models for a information contained in their initial configurations (e.g., [16]).

shows some patterns generated by evolution according to various cellular automaton rules, starting from typical disordered initial Despite the simplicity of their construction, cellular automata are found to be capable of diverse and complex behaviour. Figure 2.1

elements. But the third class gives rise to behaviour that is more complex. They can produce patterns whose features cannot readily are produced. The first two classes of cellular automata yield readily predictable behaviour, and show no seemingly random simple periodic structures (limit cycles), (3) the pattern is aperiodic, and appears chaotic, and (4) complicated localized structures conditions. Four basic outcomes are seen [15]: (1) the pattern becomes homogeneous (fixed point), (2) the pattern degenerates into nature. They can also be considered as abstract mathematical systems, and used for practical random sequence generation. be predicted in detail, and in fact often seem completely random. Such cellular automata can be used as models of randomness in

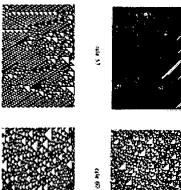

which seem most promising for explaining randomness in nature, or for use as practical random sequence generation procedures. intrinsically produce apparent randomness, without external input of random initial conditions. It is such `autoplectic" systems [11] nevertheless class 3 cellular automata which yield complex patterns, even from simple initial states. Their evolution can class 3 cellular automata yield rather simple patterns, which are typically periodic or at least self similar (almost periodic). There are instead by evolution from a very simple initial condition containing a single nonzero site. With such simple initial conditions, some initial conditions, in which the value of each site is randomly chosen to be zero or one. Figure 2.2 shows some patterns obtained Figure 2.1 shows patterns produced by evolution according to various cellular automaton rules, starting from typical disordered

computations. Effective predictions require computations that are more sophisticated than those corresponding to the cellular mathematical formulae for it. As a consequence, many questions concerning infinite time or infinite size limits cannot be answered can effectively be found only by direct simulation or observation. There are no general computational shortcuts or finite sophisticated as that of any (physically realizable) system can be [18, 19]. It is thus `computationally irreducible," and its outcome automaton evolution itself. One suspects however that the evolution of many class 3 cellular automata is in fact computationally as corresponds to a complicated computation. But any predictions of the cellular automaton behaviour must also be obtained through behaviour, while ultimately computable, may be computationally intractable, and could require, for example, exponential time by bounded computations, and must be considered formally undecidable. In addition, questions about finite time or finite size Many class 3 cellular automata seem to perform very complicated transformations on their initial conditions. Their evolution thus computations

rule 122

$_k$) in the $_{4+j}$. Such cellular automata are analogous to linear feedback shift registers [4]. An example with $_{k=2}$ is Most class 3 cellular automata are expected to be computationally irreducible. A few rules however have special simplifying features which make predictions and analysis possible. One class of such rules are those for which the function ϕ is linear (modulo

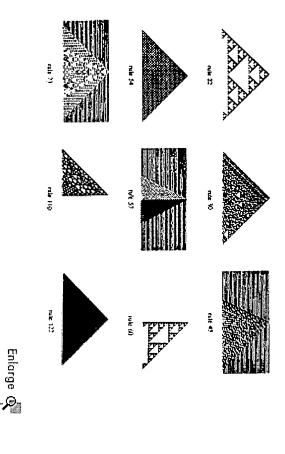

(2.4)
$$a'_i = (a_{i-1} + a_i) \mod 2 = (a_{i-1} \text{ XOR } a_i)$$

a much reduced computation possible to give a complete algebraic description of the behaviour of the system [20], and to deduce the outcome of its evolution by superpositions of the self-similar pattern produced with a single nonzero initial site (as illustrated in Fig. 2.2). As a result, it is superposition principle, which implies that patterns generated with arbitrary initial states can be obtained as appropriate where XOR stands for exclusive disjunction (this is rule number 60 in the scheme of [17]). Linear cellular automata satisfy a

mathematical results must therefore to a large extent forsake conventional mathematical techniques and instead rely on empirical and experimental their likely computational irreducibility one expects that no such methods even in principle exist. In studying such systems one Most class 3 cellular automata are however nonlinear. No general methods to predict their behaviour have been found, and from

Figure 2.2

Patterns generated by evolution of various k=2, r=1 cellular automata from an initial state containing a single nonzero site. Complex patterns are seen to be produced even with such simple initial conditions.

5. Stability Properties

configuration. The region affected increases in size with time, reflecting the instability of the patterns generated initial state. Figure 5.1 shows the differences resulting from reversal of a single site value in a typical disordered initial from all possible initial configurations. This section considers the change in the patterns produced by small perturbations in the Section 4 considered properties of possible patterns generated by evolution with the cellular automaton rule of Eq. (3.1), starting

configuration, starting from a particular point, can be represented as a real number. Linear growth of the difference pattern in Fig. information transmission to the left and right are determined by the slopes of the difference pattern in Fig. 5.1. These in turn give left and right Lyapunov exponents λ_L and λ_R for the cellular automaton evolution [15, 26]. (The sequence of site values in a 5.1 then implies exponential divergence of the numbers representing nearby configurations.) This instability implies that information on localized changes eventually propagates throughout the cellular automaton. The rates of

The form of the cellular automaton rule (3.1) immediately implies that

$$(5.1) \qquad \lambda_R = 1.$$

For consider a configuration in which the difference pattern has reached site _1. Whatever the current values of sites 0 and 1, the χ_{OR} in (3.1) leads to a change in the new value of site $_0$. The value (5.1) is the maximum allowed by the locality of the rule (3.1).

slope [45] Empirical measurements suggest that the left-hand side of the difference pattern expands at an asymptotically linear rate, with a

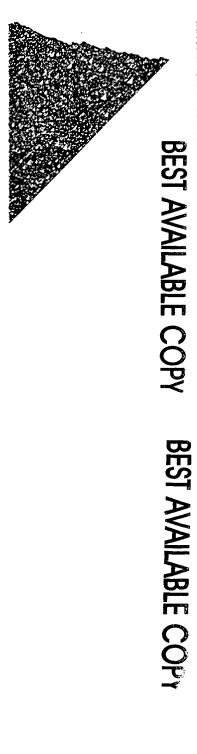

$$(5.2) \lambda_L = (0.2428 \pm 0.0003).$$

reached site 0. As a first approximation, one may assume that the motion of this front depends only on the neighbouring values 4-1 A simple statistical estimate for λ_L can be given. Consider a pair of configurations for which the front of the difference pattern has and α_{+1} , where, by construction, α_{-1} is the same for the two configurations. When $\alpha_{-1} = 0$, the front advances (left) by one site,

statistical approach discussed. (The values of λ_L obtained in this approach by considering the effects of between 1 and 5 sites on the right are 0.25, 0.1875, 0.15625, 0.140625 and 0.134766.) a single time step. This occurs when the cellular automaton rule yields the same image for multiple site value sequences, as for say biased random walk, advancing at average speed 1/4. In practice, however, Fig. 5.1 shows that the front can retreat by many sites in retreats by one site if they are unequal. If possible sets of site values occurred with equal probabilities, the front should thus follow a independent of the values of the α_1 . When $\alpha_{-1} = 1$, the front remains stationary if the α_{+1} for the two configurations are equal, and 10100 and 11001. Such phenomena make the probabilities for different difference patterns unequal, and invalidate this purely

automata. consistent with Eq. (4.6) and (5.2). The existence of positive Lyapunov exponents is a characteristic feature of class 3 cellular

approximately 1.91 + 1.19T. This result is presumably related to the entropy (4.6). approximately $0.26 \pm 0.19T$. Thus the total number of initial sites on which a length T time sequence depends is on average exponentially with distance to the right. The average number of sites on the right which affect the time sequence is found to be element of the time sequence. It seems that the probability for a particular initial site to affect the time sequence decreases change in at least one element of the time sequence. But some changes in the T right-hand initial sites have no effect on any of site values, say of length T. These sequences are always completely determined from the initial values of 2T+1 sites. But not all individual sites. In studying random sequence generation, one must also consider the effect of such perturbations on time sequences these initial values necessarily affect the time sequences. A change in any of the r_{+1} left-hand initial sites necessarily leads to a The difference pattern of Fig. 5.1, and the related Green's function, measure the effect of initial perturbations on the values of

periods of the right-hand diagonal sequences in Fig. 6.1 do seem to increase roughly exponentially with depth, as suggested by Table 6.1. This length is small compared to the total number of states 2^{N} ; few states in fact lie on such longest cycles. Nevertheless, the

depth N. Points plotted at integer N are joined for pictorial purposes Maximal period lengths Π_N for the effective cellular automaton which gives the right-hand diagonal sequences in Fig. 6.1 down to

Each site at depth d on the left-hand side of the pattern could in principle be affected by sites down to depth d arbitrarily far up in the pattern. In practice, however, it is unaffected by changes in sites outside a cone whose boundary propagates at speed $\lambda_L \simeq 0.25$. Thus the irregularity on the right spreads to the left only at this speed linear, and to move to the left with speed 0.25. A statistical argument for this result can be given in analogy with that for Eq. (5.2). The boundary in Fig. 6.1 between regular behaviour on the left and irregular behaviour on the right seems to be asymptotically

up to length $2^{19} \approx 6 \times 10^5$, and no periodicity is seen. One can prove in fact that only one such vertical sequence (obtained from any initial state containing a finite number of nonzero sites) can possibly be periodic [22]. For if two sequences were both periodic, then fact, no periodicity has been found in any such sequences. The center vertical (i.e., temporal) sequence has, for example, been tested While diagonal sequences at angles ±1 in Fig. 6.1 must ultimately become periodic, sequences closer to the vertical need not. In

it would follow that all sequences to their right must also be, which would lead to a contradiction at the edge of the pattern

statistical tests of randomness applied to it, as discussed in Section 10 Not only has no periodicity been detected in the center vertical sequence of Fig. 6.1; the sequence has also passed all other

regions of zero sites. Such regularities are associated with invariants of the cellular automaton rule While individual sequences seem random, there are local regularities in the overall pattern of Fig. 6.1. Examples are the triangular

zeroes that is produced leads to a uniform triangular region. consequence, any string of zeroes that appears can be corrupted only by effects that propagate in from its ends. Thus each string of The particular configuration in which all sites have value 0 is invariant under the cellular automaton rule of Eq. (3.1). As a

effects, and leads to a regular region in spacetime patterns generated by Eq. (3.1). iterations of the rule.) Again, any string that contains just the sequences in these configurations can be corrupted only through end Table 6.2 and Fig. 6.3 give other configurations which are periodic under the rule (3.1). (They can be considered as invariant under

Table 6.2

configurations are shown in Fig. 6.3. the four elements given for period four correspond simply to different phases in a cycle. The patterns generated by these periodic Configurations periodic under the cellular automaton mapping (3.1) consist of infinite repetitions of the elements given. Notice that

7. Functional Properties

complexity of the cellular automaton evolution. rules for say t steps correspond to functions of 2t+1 Boolean values. The complexity of these functions reflects the intrinsic Cellular automaton rules such as (3.1) can be considered as functions ϕ which map three Boolean values to one. Iterations of these

which the function is written as a disjunction of conjunctions. A two-level circuit can be constructed in direct correspondence with comparison, it is convenient to consider fixed depth representations. One such representation is disjunctive normal form (DNF), in according to the cellular automaton rule (3.1) corresponds to a circuit with $o(t^2)$ components and depth t. But for purposes of particular kind of circuit, or the number of terms that it would have in a particular symbolic representation. Explicit evolution The complexity of a Boolean function can be characterized by the number of logic gates that would be needed to evaluate it with a this form (as programmable logic arrays often are).

For the function of Eq. (3.1), the DNF is

$$(7.1) \phi(a-1, \infty, a_1) = (\overline{a-1}\infty) + (a-1\overline{\infty} \overline{a_1}) + (\overline{a-1}a_1),$$

gives a shorter form for this function. where + stands for OR, concatenation for AND, and bar for NOT. Notice that by using in addition an XOR operation, Eq. (3.1) itself

a measure of the total number of "holes" in the colouring of the n-cube, and thus of the complexity of the function. value 1. Each prime implicant can thus be used as a term in a DNF for the function. The number of prime implicants required gives implicants give the hyperplanes (with different dimensions) in the -cube which must be superimposed to obtain the region with `prime implicants" (e.g., [28]). A Boolean function of $_{n}$ variables can be considered as a colouring of the Boolean $_{n}$ -cube. Prime (e.g., [5]), and so presumably requires an exponential time computation. But a definite approximation can be found in terms of The general problem of finding the absolute shortest representation for an arbitrary Boolean function, even in DNF, is NP-complete

mapping (3.1) is The minimal DNF obtained with prime implicants for the function corresponding to two iterations of the cellular automaton

$$\phi^{2}(a_{-2}, a_{-1}, a_{0}, a_{1}, a_{2}) = (\overline{a_{-2}} \overline{a_{-1}} \overline{a_{0}} a_{1} \overline{a_{2}}) + (\overline{a_{-2}} a_{-1} a_{0} a_{1} \overline{a_{2}}) + (\overline{a_{-2}} a_{-1} a_{0} a_{1} \overline{a_{2}}) + (\overline{a_{-2}} a_{-1} a_{0} a_{1} \overline{a_{2}}) + (\overline{a_{-2}} \overline{a_{-1}} \overline{a_{0}} a_{2}) + (\overline{a_{-2}} \overline{a_{-1}} \overline{a_{0}} a$$

For arbitrary Boolean functions of 2t+1 variables, the number of prime implicants could increase like 4t. In practice, however, a Table 7.1 gives the number of prime implicants for successive iterations of the mapping (3.1). These results are plotted in Fig. 7.1. least squares fit to the data of Table 7.1 suggests growth like 40mt.

such method [28, 29], the DNF of Eq. (7.2) can be reduced to Various efficient methods are known to find DNF that are somewhat simpler than those obtained using prime implicants. With one

$$\phi^{2}(a_{-2}, a_{-1}, a_{0}, a_{1}, a_{2}) = (\overline{a_{-2}} \overline{a_{-1}} \overline{a_{0}} a_{1}) + (\overline{a_{-2}} a_{-1} a_{0} a_{1}) + (\overline{a_{-2}} a_{-1} a_{0} a_{1}) + (\overline{a_{-2}} \overline{a_{-1}} \overline{a_{0}} a_{2}) + (\overline{a_{-2}} a_{-1} a_{0} a_{2}) + (\overline{a_{-2}} a_{-1} a_{0}) + (\overline{a_{-2}} a_{-1} \overline{a_{0}}) + (\overline{a_{-2}} a_{-1} \overline{a_{0}}) + (\overline{a_{-2}} a_{-1} \overline{a_{0}}) + (\overline{a_{-2}} a_{-1} \overline{a_{0}})$$

to grow more slowly than those obtained with prime implicants; the data given are however again fit by exponential growth like The sizes of the minimal DNF obtained by this method for iterations of Eq. (3.1) are shown in Table 7.1 and Fig. 7.1. They are seen

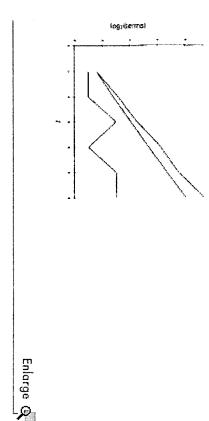

number remains much smaller, apparently increasing like 22*4(!)-1 < 22, where #1(t) gives the number of ones in the binary Table 7.1 and Fig. 7.1 also give the size of the minimal DNF for iterations of the linear cellular automaton mapping (2.4). This

representation for the integer ¿ (cf. [30]).

complexity of determining the result of evolution according to (3.1), and supports the conjecture of its computational irreducibility The rapid increase in the size of the minimal DNF found for iterations of Eq. (3.1) indicates the increasing computational (Note however that even the parity function cannot be computed by any DNF, or in general fixed-depth, circuit of polynomial size

in this case using [29]. The lowest curve gives the minimal number of terms for the linear cellular automaton mapping (2.4). curve gives the number of prime implicants for iterations of Eq. (3.1). The next curve gives the minimal number of terms obtained Number of terms in disjunctive normal form Boolean expressions for ℓ step iterations of the mappings (3.1) and (2.4). The upper

approximately as 21.384. One can also construct a function which gives the length the sequence of values of a particular site attained through time by evolution Equation (7.3) gives the function which determines the value of a single site after two iterations of the cellular automaton rule (3.1). from a given length 2t+1 initial sequence. The minimal DNF representation for this function is found (using [29]) to grow in size

about 1.2 such temporal sequences should on average be required. And in principle from a single sufficiently long temporal sites to the left can be deduced directly by iteration of Eq. (3.3). The combinatorial results of Section 4 indicate in fact that only sequence, it should be possible to deduce a complete initial configuration for a finite cellular automaton. In practice, however, the produced in the evolution. Given say $_t$ steps in the time sequence of values for two adjacent sites, the initial configuration up to $_t$ (3.1) from a given initial state. One may also consider the problem of deducing the initial state from time sequences of site values The results of Table 7.1 and Fig. 7.1 concern the difficulty of finding the outcome of cellular automaton evolution according to Eq.

sequence, for all 2t possible position 0 sequences. The number of values in the position 1 sequence on which a-t depends seems to ones, then the whole triangle of sites is completely determined, entirely independent of the position 1 sequence. Table 7.2 gives given site depends varies with the form of the position 0 sequence [32]. For example, if the position 0 sequence consists solely of as a function of values in the temporal sequence at position 1. The number of values in the position 1 temporal sequence on which a Given a particular temporal sequence, say at position 0, Eq. (3.3) uniquely determines the values of all sites in a triangle to the left be roughly Poisson distributed, with a mean that grows like 0.4%, as shown in Fig. 7.2. This is consistent with the combinatorial some results from considering the dependence of the site value α_{-t} at position -t (the apex of the triangle) on the position is

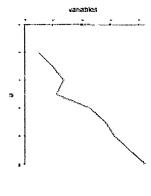

result (4.6). Table 7.2

prime implicants in the disjunctive normal form for the expression. The maximum number of variables which can appear is always according to Eq. (3.1). The average number of variables appearing in the Boolean expressions is given, together with the number of Properties of Boolean expressions for leftmost initial site values deduced from length , time sequences, obtained by evolution n_{-1} . 8. Computation Theoretical Properties

explicit simulation of each time step. As discussed above, one suspects in fact that the evolution is in general computationally of the cellular automaton mapping (3.1) in a particular simple model of computation. The results obtained suggest that at least in The discussion of the previous section can be considered as giving a characterization of the computational complexity of iterations irreducible, so that no possible computation could find its outcome more efficiently than by direct simulation this model, there is no shortcut method for finding the outcome of the evolution: the computations required are no less than for an

on any computer. (Direct simulation takes $o(t^2)$ time on a serial-processing computer, and o(t) time with o(t) parallel processors.) appropriate initial state, its evolution could mimic any possible computation. In particular, it could be that the problem of finding cellular automaton of Eq. (3.1) it quite probably cannot [18]. For a linear cellular automaton such as that of Eq. (2.4), this problem can be solved in a time polynomial in $\log(t)$; but for the the value of a particular site after t steps (given say a simply-specified initial state, as in Fig. 6.1) must take a time polynomial in t This would be the case if the cellular automaton of Eq. (3.1) could act as an efficient universal computer (e.g., [33]), so that with ar

configurations of the cellular automaton from partial information such as temporal sequences. In particular, one may study the computational complexity of finding the seed for a cellular automaton in a finite region from the temporal sequences it generates In addition to studying cellular automaton evolution from given initial configurations, one may consider the problem of deducing

can then be deduced by solving the resulting system of simultaneous Boolean equations. The equations will however typically size system, say with periodic boundary conditions, one can derive many distinct equations for a single site value. The site value more efficient method. If it were possible to find two adjacent temporal sequences, then the seed could be found easily using Eq. trying each of them in turn. Such a procedure would however rapidly become impractical. The results in Section 7 suggest a slightly involve many variables. As discussed in Section 7, the number of variables seems to be Poisson-distributed with a mean around (3.3). Given only one temporal sequence, however, some elements of the seed are initially undetermined. Nevertheless, in a finite There are 2^M possible seeds for a size M cellular automaton, and one can always find which ones produce a particular sequence by

conceivable that the problem of deducing the seed is equivalent to the general problem of solving Boolean equations, which is NPtypically involves 0(2°), but these seem to have no special simplifying features. At least with the method discussed above, it is thus equations generated were in a sense uniformly distributed over all possibilities. Out of all 22 re-variable equations, the problem here a time polynomial in _{re}. In addition, it seems likely that the average time to solve an arbitrary Boolean equation is correspondingly long. To relate the problem of deducing the seed discussed above to this would however require a demonstration that the Boolean The general problem of solving a Boolean equation in n variables is NP-complete (e.g., [5]), and so presumably cannot be solved in

there are two more with zero predecessors when 3|M. For large M, the number of configurations with zero or two predecessors unless N is divisible by 3, and all sites have value one. In the former case, the configuration has exactly zero or two predecessors; in unique predecessor unless it contains a pair of value zero sites separated by a sequence of 3n+1 value one sites (with $n \ge 0$), or behaves as [32] κ^{N} , where $\kappa \simeq 1.696$ is the real root of $4\kappa^{3} - 2\kappa^{2} - 1 = 0$. Since the total number of configurations grows like 2^{N} , the the latter case, it has three. The numbers of configurations with zero and two predecessors are equal when $_N$ is not divisible by 3; in Section 4), so there is little branching in the state transition diagram. In fact, it can be shown [32] that a configuration has a A first observation is that most configurations have unique predecessors under the mapping (3.1) (as mentioned for infinite lattices fraction of nodes in the state transition diagram that are branch points thus tends exponentially to zero

Figure 9.1

state transition diagrams are given in Table 9.1. (Graphics by Steve Strassmann.) mapping. Transients corresponding to trees in the graph are seen ultimately to evolve to periodic cycles. Some properties of these node represents one of the 2^N possible length N configurations, and is joined by an arc to its successor under the cellular automaton State transition diagrams for configurations of cellular automata evolving according to Eq. (3.1) in circular registers of size N. Each

Enlarge 🔎

A second observation is that there are often many identical parts in the state transition diagrams of Table 9.1 and Fig. 9.1. This is largely a consequence of shift invariance. States in a cellular automaton with periodic boundary conditions that are related by shifts

configurations related by shifts. The transient trees that feed each of these sequences are then identical configurations. In addition, the periods of the cycles are often divisible by w or its factors, since they contain several sequences of (translations) evolve equivalently. Thus, for example, there are often several identical cycles, related by shifts in their

these factors. periods occur whenever N is divisible by the spatial periods of these configurations. Such short cycles are absent if N has none of inverse to those in Table 6.2 on configurations with given temporal periods. Cycles of lengths corresponding to these temporal automaton with a periodic initial configuration. Thus the results on cycle length distributions in Table 9.1 can be considered as The evolution of a finite cellular automaton with periodic boundary conditions is equivalent to the evolution of an infinite cellular

branching in the transient trees implies that the points reached from arbitrary initial states should be roughly uniformly distributed than the others, and its basin of attraction is large enough that most arbitrarily chosen initial states evolve to it. The low degree of For large N, the state transition diagrams for Eq. (3.1) appear to be increasingly dominated by a single cycle. This cycle is longer

expected to have these properties, and thus to be trapped in subsets of state space, and to yield short cycles. For example, with symmetry properties that are preserved by the cellular automaton rule. Initial states with particular, symmetrical, forms can be yield shorter cycles. (This phenemonon also occurs for cellular automata with essentially trivial rules, such as the shift mapping same type. Once such a configuration has been reached, the evolution is ``trapped" within this subset of configurations, and must even, for example, configurations which consist of two identical length N/2 subsequences can evolve only to configurations of the which are inequivalent under shifts or rotations. These necklaces in turn correspond to cyclotomic polynomials; there are The shorter cycles in Table 9.1 can be considered as related to subsets of states invariant under the cellular automaton rule. With _M longest cycle, with 2237472 states. $\alpha'_{i} = \alpha_{i}$. All states are on cycles in this case. The different cycles correspond to the possible `necklaces' with N beads of two kinds, N=36, a configuration containing a single nonzero site evolves to a length 2844 cycle, while most initial configurations evolve to the $\sum_{d|m} \phi(d)^{2N/d}$ of them, where ϕ the Euler totient function (e.g., [4]).) In general, there may exist subsets of states with certain special

But with a total of N sites, a cycle must occur after 2^N or less steps. Table 9.2 and Fig. 9.2 give the actual maximal cycle lengths Π_N found. A roughly exponential increase of Π_N with N is seen, and a least squares fit to the data of Table 9.2 yields In the infinite size limit, patterns such as that of Fig. 6.1 generated by the cellular automaton of Eq. (3.1) never become periodic

$(9.1) \qquad \log_2 \Pi_N \simeq 0.61(N+1).$

cycles of average length 2M would be expected [34]. The cycles actually obtained are significantly longer. The exponent in Eq. Note that if the state transition diagram corresponded to an entirely random mapping between the 2^M cellular automaton states, then (9.1) may be related to the entropy (4.6) as a result of the expansivity or instability of the mapping discussed in Section 5

say whether two configurations lie on the same cycle is PSPACE-complete, and so presumably cannot be solved in a time required to determine for example the lengths of cycles that appear. For in this case, there can effectively be no better way to find the cycles studied are $O(2^{M})$, where both 2^{M-M} and 2^{M} are large, then parallel processing is essentially of no avail in this problem.) polynomial in _N, but rather essentially requires a direct simulation of the cellular automaton evolution. (Note that if the lengths of the succession of states that occur, except by explicit application of the rule (3.1). One expects in fact that the problem of finding If indeed the evolution of cellular automata such as (3.1) is computationally irreducible, then a complex computation may always be

should be much easier for linear cases such as (2.4). From the algebraic theory of these systems it is possible to show for example that the maximal cycle length Π_N satisfies [20] While the determination of cycle lengths and structures may be computationally intractable for cellular automata such as (3.1), it

(9.2)
$$\Pi_N(2^{\operatorname{ord}_N(2)} - 1,$$

relatively prime to N), which is maximal for prime N. Table 9.2 and Fig. 9.2 give the actual maximal periods found in this case where Am states that the integer re exactly divides m. Here order function, equal to the minimum integer rule (3.1). Equation (9.2) rarely holds as an equality, and the Π_N found are usually much shorter than the corresponding ones for the nonlinear such that $k^j = 1 \mod N$. This function divides the totient function $\phi(N)$ (equal to the number of integers less than N which are

three-dimensional view is from the point N = L = 20, with elevation 2. Fraction of length L sequences obtained by evolution from all possible seeds according to Eq. (3.1) in a size N circular register. The

of entropy deduced from a finite sample is thus almost always not maximal, even if it would be maximal were the sequence to be not random. One can however calculate the probability that a truly random sequence would have the properties seen in the finite continued forever.) As a consequence, one can never definitively conclude by studying a finite sample that the complete sequence is of length m, there are expected to be statistical fluctuations, which lead to slightly different numbers of zeroes and ones. (The value equal frequency. (The measure entropy of (4.2) is maximal exactly when such equidistribution occurs.) However, in a finite sample and one must occur in it with equal frequency. In general, in fact, all 2 possible length blocks of digits must also occur with As an example, consider the `equidistribution" or `frequency" test. If a sequence of zeroes and ones is to be random, the digits zero

Enlarge Q

To do this (e.g., [36]), one evaluates χ^2 , defined in terms of the observed and expected frequencies p_0 and p_s as

(10.1)
$$\chi^2 = \sum_{1} (p_0 - p_c)^2 / p_c$$

of length $_{R}$ are studied then $_{V}=2^{R}$. Now one must find the probability that a value of $_{X}^{2}$ larger than that observed would occur for a random sequence. This `confidence interval" is obtained immediately from the integral of the χ^2 distribution (e.g., [36]). Here , gives the number of degrees of freedom, or number of distinct objects whose frequencies are included in the sum. If blocks

excess of confidence interval values close to zero or one, over and above the number expected for a uniform distribution. confidence interval for at least one of them will be less than 1/k. Evidence for nonrandomness in a sequence must come from an one may infer that the observed sequence is not random. Of course, if say a total of k tests are done, it is to be expected that the If the confidence interval is very close to zero or one, then the observed χ^2 is unlikely to be produced from a random sequence, and

a finite circular register. Except when the sample sequence is comparable in length to the period of the system, as given by Table Table 10.1 gives results from the statistical tests described in Appendix A for sequences generated by the cellular automaton (3.1) in

9.2, no significant deviations from randomness are found.

regularities are detected in the digit sequence of $\sqrt{2}$ (and other surds tried) (cf. [37]). There is, however, some possible evidence for nonrandomness in the digit sequences of $_{\sigma}$ and $_{\pi}$ (cf. [38]). (This will be explored elsewhere.) sequences obtained from linear congruential generators are also found to be significantly nonrandom with respect to these tests. No while provably random in some respects (e.g., [4]), are revealed as significantly nonrandom by several of the tests used here. Many Table 10.2 gives statistical results for sequences generated by other procedures. Those obtained from linear feedback shift registers,

from a single nonzero initial site on an infinite lattice. Once again, no significant deviations from randomness are seen Table 10.3 gives statistical results for temporal sequences in the pattern of Figure 6.1 obtained by evolution according to Eq. (3.1)

demonstrate that the sequence did not have maximal information content. The fact that deviations from randomness have not been predictions about the sequence. In addition, it could be used to obtain a compressed representation for the sequence, and would thus If deviations from randomness were detected by some statistical procedure, then this procedure could be used to make statistical found by any of the statistical procedures considered lends strong support to the belief that sequences produced by Eq. (3.1) with

large N are indeed random for practical purposes.

11. Practical Implementation

of computers The simplicity and intrinsic parallelism of the cellular automaton rule (3.1) makes possible efficient implementation on many kinds

represented by single bits in say a 32-bit word, and updated in parallel using standard word-wise Boolean operations. (Additional bit-wise operations are often needed for boundary conditions.) On a serial-processing computer, each site could be updated in turn according to (3.1). But in practice, site values can be

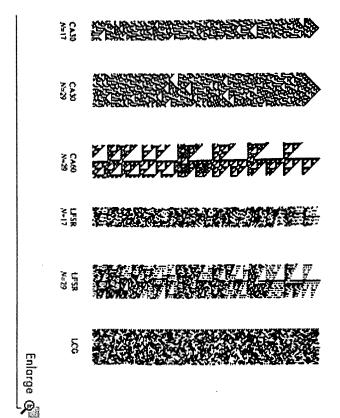

different processors. They can then be updated independently (though synchronously), using the same instructions, and with only On a synchronous parallel-processing computer, different sites or groups of sites in the cellular automaton can be assigned to local communications

each site. And for long registers, a pipelined approach analogous to a feedback shift register can be used (cf. [39]) Very efficient hardware implementations of (3.1) should also be possible. For short registers, explicit circuitry can be included for

cycle length. To obtain a cycle length larger than $2^{20} \simeq 4 \times 10^9$, Table 9.2 shows that a circular register of length N = 49 can be used be to obtain a cycle length larger than $2^{64} \simeq 10^{19}$. But based on Eq. (9.1), a value N = 127 should certainly suffice Cycle lengths tend to increase with N, but Table 9.2 shows some irregularities. Thus it is not clear, for example, how large N need The most appropriate detailed choices of parameters depend on the application intended. The most obvious constraint is one of The evidence presented above suggests that the cellular automaton of Eq. (3.1) can serve as a practical random sequence generator.

generates a sequence more slowly, it should foil prediction procedures along the lines discussed in Section 7 some critical applications, it may be best however, to sample site values only say on alternate time steps. While this method (3.1). The theoretical and statistical studies described above support the contention that such sequences show no regularities. For Random sequences can be obtained by sampling the sequence of values of a particular site in a register updated according to Eq.

produced are given in Tables 10.1 and 10.2. given. The seed in all cases consists of a single nonzero bit in the center of the register. Statistical properties of the sequences 27 and 29. LCG is a linear congruential sequence generator, operating on the 32-bit integers whose binary digit sequences are boundary conditions. CA60 is the linear cellular automaton of Eq. (2.4), again with periodic boundary conditions. LFSR is a linear Patterns obtained by various procedures in registers of size $_{N}$. CA30 stands for the cellular automaton of Eq. (3.1), with periodic feedback shift register with size N and period $2^N - 1$. For N = 17 the taps are at positions 14 and 17; for N = 29, they are at positions

BEST AVAILABLE COPY

differential equations, where randomness can be used to emulate additional low-order digits.) sites sampled are equally spaced around the register. Nevertheless, in some applications where only a low degree of randomness is Eq. (4.6) implies that some statistical correlations must exist between these values. The correlations are probably minimized if the Sequences could potentially be obtained more quickly by extracting the values of several sites in the register at each time step. But needed, it may even be satisfactory to use all site values in the register. (An example appears to be approximation of partial

binary choices with unequal probabilities. There is nevertheless a simple algorithm [40] to obtain digits with arbitrary probabilities First write the probability p for outcome 1 as a binary number. Then generate a random binary sequence, with a length equal to The random sequences obtained from Eq. (3.1) have an equal fraction of 0 and 1. Many applications, however, involve random

AND or OR, depending on whether the digit in p is 0 or 1, respectively. The final result thus obtained is equal to 1 with probability significant digit in p, successively find a new result by combining the old result with the corresponding digit of s, using a function this number. The output is obtained by an iterative procedure. Begin with a `current result" of 1. Then, starting from the least

addresses of computer elements), then (3.1) should be applied at least O(N) times to the seeds before beginning to extract random and should be ~0.8N. Thus, if several sequences are to be generated with seeds that differ only slightly (obtained for example from Configurations in two length y registers with slightly different seeds should become progressively less correlated under the action (3.1) as a result of the instability discussed in Section 5. The characteristic time for this process is governed by Eqs. (5.1) and (5.2),

proofs for particular randomness properties can be given, and it must be investigated by largely empirical methods and no significant limits on the degree of randomness it yields are known. But on the other hand, no conventional mathematical of randomness that such schemes can produce. The nonlinear scheme described here is not readily amenable to complete analysis, and cases that give long cycles can be identified. But the simplicity in structure which underlies this analysis also limits the degree analysed by algebraic methods. As a consequence, certain randomness properties can be proved for the sequences they generate, One may compare the scheme for random sequence generation described here with the linear methods now in common use (e.g., [1]). Figure 11.1 shows patterns produced by these various schemes. The primary feature of linear schemes is that they can be

Random Sequence Generation by Cellular Automata (1986)

12. Alternative Schemes

automata may also be considered, and some potentially have certain advantages The cellular automaton of Eq. (3.1) is one of the simplest that seems good for random sequence generation. But other cellular

Among k = 2, k = 1 cellular automata, Eq. (3.2) is the only other serious contender. No direct equivalence between this rule and that of Eq. (3.1) is known, but their properties are very similar. Equation (3.2) gives however [45]

(12.1)
$$\lambda_L = (0.1724 \pm 0.0004),$$

seems to have no advantages over (3.1). slightly smaller than the corresponding result (5.2) for Eq. (3.1). In addition, it gives a slightly smaller invariant entropy h,. It

exponents and invariant entropies than Eq. (3.1), but they are also more difficult to compute. In addition, many rules that seem to which produce complex patterns even from simple initial conditions are probably best. Some of these rules have larger Lyapunov temporal entropies. Permutive chaotic rules avoid such problems, but are very similar in character to the rule of Eq. (3.1), and so produce chaotic overall patterns nevertheless yield sequences that show definite regularities, resulting, for example, in non-maximal the rule.) Any class 3 (chaotic) cellular automaton rule can be considered a candidate random sequence generator. Autoplectic rules Cellular automata with k > 2 or R > 3 may also be studied. (Here R is defined as the total number of sites in the neighbourhood for

potentially share any of its possible deficiencies.

13. Discussion

essentially arbitrary complexity. And it seems likely that the mathematical mechanisms at work are also responsible for much of the with the observation that mathematical systems with few axioms, or computers with few intrinsic instructions, can lead to seem random for practical purposes. It is remarkable that such a simple system can give rise to such complexity. But it is in keeping Despite the simplicity of its construction, all the approaches taken support the conjecture that its behaviour is so complicated as to This paper has used methods from several disciplines to study the behaviour of the nonlinear cellular automaton of Eq. (3.1). randomness and chaos seen in nature.

suggest that the sequences it produces have a high degree of randomness. In fact, if any regularity could be found in these sequences, it would probably have substantial consequences for studies of many complex and seemingly random phenomena The simplicity of Eq. (3.1) makes it amenable to highly efficient practical implementation. And the analyses carried out here

व्यादकः या अवध्यक्षां वाद्यां विद्यात

- difficulty of finding them. None of the sequences discussed here, nor many generally considered random, would qualify according (1) A stricter definition of randomness can be based on the non-existence of simple descriptions [3], rather than merely the
- behaviour is more complicated, and is related to the so-called 3N + 1 problem [9]. (2) This operation can be performed locally on a base 6 digit sequence, and so can be implemented as a cellular automaton. Given particular finite boundary conditions, it acts like a linear congruential sequence generator (e.g., [1]). But in an infinite region, its
- (3) Recent results [45] suggest in fact that $h_{\mu} \simeq 1 + T^{-(0 \leftrightarrow 0.1)}$, yielding a final value of 1.
